

Development, wellbeing, and the measurement problem

Significance is Benjamini-Hochberg FDR-corrected within country.

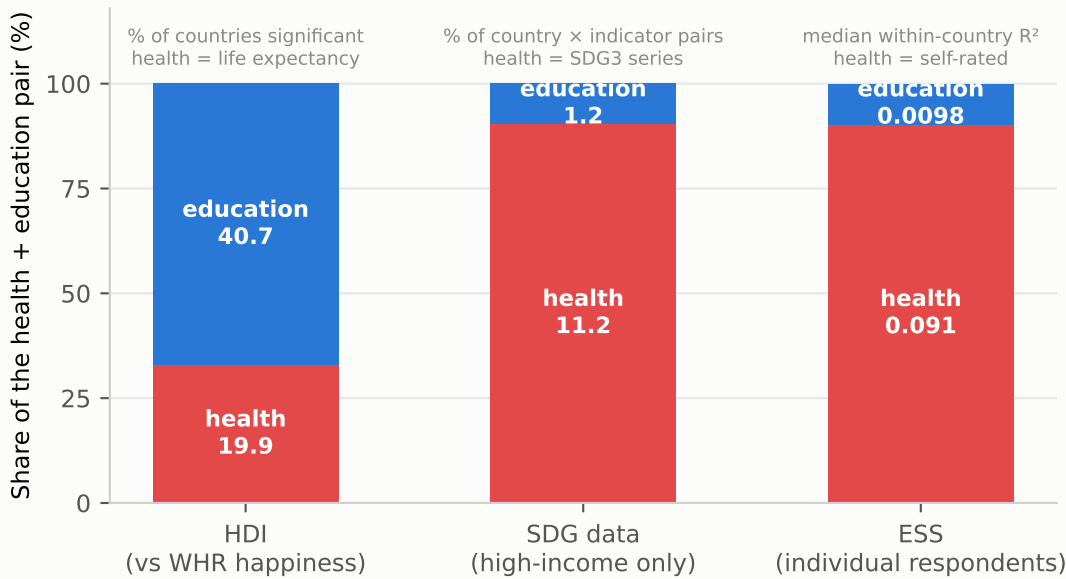

a The collapse is not an artifact of the SDG framework

One outcome (WHR Cantril ladder). The SDG test asks whether ANY of a country's series is significant, so its levels rate is higher by construction — the collapse ratio is what compares. Also replicates against a second wellbeing survey and at regional scale (Act I).

b The ranking inverts with the instrument

Each instrument uses its own metric (noted above each bar), so only the ordering compares. Education leads under the HDI; health leads by an order of magnitude in both sources that measure it somewhere it still varies.

c Only health leads in both an administrative and a self-report source

Labels give the raw values: % of SDG country × indicator pairs significant, and median within-country R² across ESS respondents. Trust ranks second in the self-report source and near the bottom of the administrative one — the SDG framework has no interpersonal-trust indicator at all. Education is weak in both.
